Reactive Power Control of Permanent-Magnet Synchronous Wind Generator With Matrix Converter

Hossein Hojabri, Hossein Mokhtari, Member, IEEE, and Liuchen Chang, Senior Member, IEEE

Abstract—In this paper, the reactive power control of a variable-speed permanent-magnet synchronous wind generator with a matrix converter at the grid side is improved. A generalized modulation technique based on singular value decomposition of the modulation matrix is used to model different modulation techniques and investigate their corresponding input reactive power capability. Based on this modulation technique, a new control method is proposed for the matrix converter which uses active and reactive parts of the generator current to increase the control capability of the grid-side reactive current compared to conventional modulation methods. A new control structure is also proposed which can control the matrix converter and generator reactive current to improve the grid-side maximum achievable reactive power for all wind speeds and power conditions. Simulation results prove the performance of the proposed system for different generator output powers.

Index Terms—Matrix converter, permanent-magnet synchronous generator (PMSG), reactive power control, singular value decomposition (SVD) modulation, variable-speed wind generator.

I. INTRODUCTION

A MATRIX converter is a direct ac/ac frequency converter which does not require any energy storage element. Lack of bulky reactive components in the structure of this all silicon-made converter results in reduced size and improved reliability compared to conventional multistage ac/dc/ac frequency converters. Fabrication of low-cost and high-power switches and a variety of high-speed and high-performance digital signal processors (DSPs) have almost solved some of the matrix converter drawbacks, such as complicated modulation, four-step switching process of bidirectional switches, and the use of a large number of switches [1]. Therefore, its superior benefits, such as sinusoidal output voltage and input current, controllable input power factor, high reliability, as well as a small and packed structure make it a suitable alternative to back-to-back converters.

One of the recent applications of matrix converters is the grid connection of variable-speed wind generators [2]–[14]. Variable-speed permanent-magnet synchronous (PMS) wind generators are used in low-power applications. The use of a matrix converter with a multipole PMSG leads to a gearless, compact, and reliable structure with little maintenance which is superior for low-power microgrids, home, and local applications [13], [15]–[17].

The wind generator frequency converter should control the generator-side quantities, such as generator torque and speed, to achieve maximum power from the wind turbine, and the grid-side quantities such as grid-side reactive power and voltage to improve the system stability and power quality (PQ) [17]–[19]. Unlike conventional back-to-back converters in which a huge dc-link capacitor makes the control of the generator and grid-side converters nearly independent [20], a matrix converter controls the generator and grid-side quantities simultaneously. Therefore, the grid-side reactive power of a matrix converter is limited by the converter voltage gain and the generator-side active or reactive power [21].

One necessary feature for all generators and distributed generators (DGs) connecting to a grid or a microgrid is the reactive power control capability. The generator reactive power can be used to control the grid or microgrid voltage or compensate local loads reactive power in either a grid-connected or an islanded mode of operation [19], [20]. In this paper, the grid-side reactive power capability and control of a PMS wind generator with a matrix converter is improved. For this purpose, in Section II, a brief study of a matrix converter and its singular value decomposition (SVD) modulation technique, which is a generalized modulation method with more relaxed constraints compared to similar modulation methods, is presented.

In Section III, the SVD modulation technique is used to model different modulation techniques and study the reactive power capability of a matrix converter. It is shown that in some modulation techniques, such as Alesina and Venturini, the grid-side reactive current is synthesized only by the reactive part of the generator-side current. In other modulation techniques, such as indirect methods or direct and indirect space vector modulation (SVM) methods, the grid-side reactive current is synthesized only by the active part of the generator-side current. To increase the matrix converter reactive current gain, the SVD modulation technique is used such that both active and reactive parts of the generator-side current can contribute to the grid-side reactive current.

It is shown in Section IV that the generator free reactive power capacity can be used to increase the grid-side reactive power. A new control structure is also proposed which can control the generator and matrix converter reactive power to increase the controllability of the grid-side reactive power at any...
wind speed and power. The proposed control structure is simulated with a simple adaptive controller (SAC) on a gearless multipole variable-speed PMS wind generator, and the results are presented to verify its performance under different operating conditions. The simulations are performed using PSCAD/EMTDC software.

II. MATRIX CONVERTER

Fig. 1 shows a typical three-phase matrix converter. In a matrix converter, the input and output phases are related to each other by a matrix of bidirectional switches such that it is possible to connect any phase at the input to any phase at the output. Therefore, the controllable output voltage is synthesized from discontinuous parts of the input voltage source, and the input current is synthesized from discontinuous parts of the output current source or

\[
V_{i,ABC} = SV_{i,ABe} \quad I_{i,ABe} = S^T I_{o,ABC}
\]

where \(S = \begin{pmatrix} s_{11} & s_{12} & s_{13} \\ s_{21} & s_{22} & s_{23} \\ s_{31} & s_{32} & s_{33} \end{pmatrix} \) and \(s_{kj} \) is the switching function of switch \(k_j\).

Lack of an energy storage component in the structure of a matrix converter leads to an equality between the input–output active power, i.e.,

\[
\begin{align*}
P_i &= V_{i,ABe}^T I_{i,ABe} = V_{o,ABC}^T I_{o,ABC} = P_e.
\end{align*}
\]

A. SVD Modulation Technique

Different modulation techniques are proposed for a matrix converter in the literature [21]–[23]. A more complete modulation technique based on SVD decomposition of a modulation matrix is proposed in [24]. Other modulation methods of a matrix converter can be deduced from this SVD modulation technique. The technique proposed in [24] has more relaxed constraints compared to other methods.

The SVD modulation method is a duty cycle method in which the modulation matrix \(M\), which is defined in (3), is directly constructed from the known input voltage and output current and desired output voltage and input current, i.e.,

\[
\begin{align*}
M &= A_{ve} \{ s \} = \begin{pmatrix} m_{11} & m_{12} & m_{13} \\ m_{21} & m_{22} & m_{23} \\ m_{31} & m_{32} & m_{33} \end{pmatrix} \\
\{ 0 \leq m_{kj} \leq 1 \\ m_{k1} + m_{k2} + m_{k3} = 1 \} \\
k, j = 1, 2, 3
\end{align*}
\]

where \(m_{kj}\) is the average of \(s_{kj}\) over a switching period.

To represent the input and output voltages and currents in space vector forms, all quantities of the input and output of the matrix converter are transferred from the \(abc\) reference frame to the \(\alpha\beta\) reference frame by the modified Clarke transformation of (4). Therefore, the new modulation matrix \(M_{\alpha\beta0}\) is obtained as

\[
\begin{align*}
V_{o,\alpha\beta0} &= M_{\alpha\beta0} V_{i,\alpha\beta0} \\
I_{i,\alpha\beta0} &= M_{\alpha\beta0}^T I_{o,\alpha\beta0} \\
M_{\alpha\beta0} &= K M_{abc} K^T \\
K &= \sqrt{\frac{2}{3}} \begin{pmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \\ 0 & \frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} \end{pmatrix} \\
K^{-1} &= K^T \text{or} \quad KK^T = I.
\end{align*}
\]

The last equality means that matrix \(K\) is a unitary matrix or its transpose is equal to its inverse. Considering the condition set by (3) and using (4), the following basic form for the \(M_{\alpha\beta0}\) is obtained:

\[
\begin{align*}
M_{\alpha\beta0} &= K M_{abc} K^T \\
&= \begin{pmatrix} g_{11} & g_{12} & 0 \\ g_{12} & g_{22} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ c_1^* c_2^* \\ 1 \end{pmatrix} \\
&= \begin{pmatrix} M_{\alpha\beta2} & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \end{pmatrix} \begin{pmatrix} C_{1x2} \end{pmatrix} M_0
\end{align*}
\]

where \(M_{\alpha\beta}\) generates \(V_{o,\alpha\beta}\) and \(I_{i,\alpha\beta}\) from \(V_{i,\alpha\beta}\) and \(I_{o,\alpha\beta}\), and \(M_0\) generates \(V_{o,\alpha\beta}\) and \(I_{i,\alpha\beta}\) from \(V_{i,\alpha\beta}\) and \(I_{o,\alpha\beta}\), respectively.

Since, in a three-phase three-wire system, no zero-sequence current can flow, the zero-sequence voltage can be added to the output phase voltages to increase the flexibility of the control logic. Therefore, in all modulation methods, the main effort is devoted to selecting suitable \(M_{\alpha\beta}\) in (6) to control the output voltage and input current and a suitable \(M_0\) to increase the operating range of the matrix converter, i.e.,

\[
\begin{align*}
\begin{pmatrix} v_{a0} \\ v_{0\beta} \end{pmatrix} &= \begin{pmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{pmatrix} \begin{pmatrix} v_{\alpha} \\ i_{\beta} \end{pmatrix} \\
\begin{pmatrix} i_{\alpha} \\ i_{0\beta} \end{pmatrix} &= \begin{pmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{pmatrix} \begin{pmatrix} v_{\alpha} \\ i_{\beta} \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} v_{a0} \\ v_{0\beta} \end{pmatrix} = \begin{pmatrix} C_{1x2} \end{pmatrix} M_0
\end{align*}
\]
Fig. 2. Concept of the SVD of a matrix.

$$M_{\alpha\beta}$$ maps $$V_{\alpha\beta}$$ from the input $$\alpha\beta$$ space onto $$V_{\alpha\beta}$$ in the output $$\alpha\beta$$ space and $$M_{\alpha\beta}^T$$ maps $$I_{\alpha\beta}$$ from the output $$\alpha\beta$$ space onto $$I_{\alpha\beta}$$ in the input $$\alpha\beta$$ space. Each matrix can be decomposed into a product of three matrices as shown in (7) which is called SVD of a matrix [25]

$$M = U_o \Sigma U_i^*$$

$$\Sigma = \begin{pmatrix} \sigma_1 & 0 \\ 0 & \sigma_2 \end{pmatrix}, \begin{pmatrix} U_{\alpha,2x2} = (U_{\alpha,1x1}) \quad U_{\alpha,2x1} \end{pmatrix}, \begin{pmatrix} U_{\alpha,2x2} = (U_{\alpha,1x1}) \quad U_{\alpha,2x1} \end{pmatrix}$$

$$U_i U_i^* = U_o U_o^* - I$$

(7)

where $$U_i$$ and $$U_o$$ are unitary matrices meaning that their columns are orthonormal vectors, and the $$\ast$$ operator is conjugate transpose. $$\sigma_1$$ and $$\sigma_2$$ are the gains of matrix $$M$$ in the direction of $$U_{\alpha,1x1}$$ and $$U_{\alpha,2x2}$$.

As Fig. 2 depicts, the SVD of a matrix means that this matrix will transform the vectors in the direction of $$U_{\alpha,1x1}$$ toward the direction of $$U_{\alpha,2x2}$$ by a gain of $$\sigma_1$$ and vectors in the direction of $$U_{\alpha,2x2}$$ toward the direction of $$U_{\alpha,1x1}$$ by a gain of $$\sigma_2$$.

As presented in Fig. 3, $$M_{\alpha\beta}$$ also has an SVD decomposition where $$U_{\alpha,2x2}$$ and $$U_{\alpha,2x1}$$ are orthonormal vectors rotating at a speed equal to the input frequency (i.e., $$U_{\alpha,d}$$ and $$U_{\alpha,q}$$, and $$U_{\alpha,2x1}$$ and $$U_{\alpha,2x2}$$ are orthonormal vectors rotating at the output frequency, that is, $$U_{\beta,d}$$ and $$U_{\beta,q}$$).

$$\begin{pmatrix} U_{\alpha,d} \quad U_{\alpha,q} \end{pmatrix} = \begin{pmatrix} \cos \theta \quad -\sin \theta \\ \sin \theta \quad \cos \theta \end{pmatrix} \begin{pmatrix} U_{\alpha,2x2} = (U_{\alpha,1x1}) \quad U_{\alpha,2x1} \end{pmatrix}$$

$$\times \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}^T$$

(8)

By substituting (8) into (5), $$M_{abc}$$ is obtained as

$$M_{abc} = K^T M_{\alpha\beta} K - K^T M_{\alpha\beta} K + K^T M_0 K$$

$$- M_{abc, \alpha\beta} + M_{abc,0}$$

$$- \mathbf{P}(\theta_i)^T \begin{pmatrix} q_d & 0 \\ 0 & q_q \end{pmatrix} \mathbf{P}(\theta_i) + M_{abc,0}$$

$$\mathbf{P}(\theta) = \sqrt{\frac{2}{3}} \begin{pmatrix} \cos \theta & \cos(\theta - \frac{2\pi}{3}) & \cos(\theta + \frac{2\pi}{3}) \\ -\sin \theta & -\sin(\theta - \frac{2\pi}{3}) & -\sin(\theta + \frac{2\pi}{3}) \end{pmatrix}$$

(9)

where $$\mathbf{P}(\theta)$$ is the modified Park transformation matrix.

It can be proved that if the following limitation on $$q_d$$ and $$q_q$$ is held, there exists a $$M_{abc,0}$$ matrix for which the condition of (3) is correct [24]. Therefore

$$\max \{|q_d|, |q_q| \leq \frac{2\pi}{3}\} \Rightarrow$$

$$\begin{cases} 0 \leq m_{kj} \leq 1 \\ m_{k1} + m_{k2} + m_{k3} = 1 \quad k, j = 1, 2, 3 \end{cases}$$

(10)

There may be many solutions for matrix $$M_{abc,0}$$; however, the following solution requires simple calculations [24]:

$$M_{abc,0} = \begin{pmatrix} c_1 & c_2 & c_3 \\ c_1 & c_2 & c_3 \\ c_1 & c_2 & c_3 \end{pmatrix}$$

$$c_k = -\min \left\{ \{M_{abc,\alpha\beta}(1, k)\} \right\}$$

$$+ \left\{ 1 + \sum_j \min \left\{ \{M_{abc,\alpha\beta}(1, j)\} \right\} \right\}$$

$$\cdot 3 - \sum_j \max \left\{ \{M_{abc,\alpha\beta}(1, j)\} \right\} + \sum_j \min \left\{ \{M_{abc,\alpha\beta}(1, j)\} \right\}$$

(11)

The constraint obtained in (10) is an inherent constraint of a matrix converter which is more relaxed than the constraint of conventional modulation methods. Therefore, the use of the SVD modulation technique can improve the performance of a matrix converter when the input reactive power control is needed [23], [24].

All of the existing modulation methods can be deduced from this simple and general method by choosing suitable $$q_d$$, $$q_q$$, $$\theta_i$$, and $$\theta_o$$. On the other hand, (9) shows that if the input and output quantities are transferred onto their corresponding synchronous reference frames, the SVD modulation matrix becomes a simple, constant, and time-invariant matrix (i.e., $$M_{dq}$$). Therefore, as shown in Fig. 4, the SVD modulation technique models the matrix converter as a $$dq$$ transformer in the input–output synchronous reference frame.
III. MATRIX CONVERTER REACTIVE POWER CONTROL

Several control strategies based on different modulation techniques can be used to control the input reactive current and power of a matrix converter. All modulation techniques can be modeled by the SVD modulation method. Therefore, this method can be used to study the reactive power capability and control of a matrix converter.

According to Fig. 3, the input reactive power of a matrix converter can be written in a general form as [26]

\[
Q_i = Q_{id} + Q_{iq}
\]

(12)

where \( S_i \) is the input complex power, \( Q_{id} \) is the part of the input reactive power made from \( I_{id} \), and \( Q_{iq} \) is the part of the input reactive power made from \( I_{iq} \).

Therefore, the following three different strategies of synthesizing the input reactive power of a matrix converter can be investigated:

- Strategy 1: synthesizing from the reactive part of the output current (i.e., \( Q_{iq} \));
- Strategy 2: synthesizing from the active part of the output current (i.e., \( Q_{id} \));
- Strategy 3: synthesizing from the active and reactive parts of the output current (i.e., \( Q_{id} + Q_{iq} \)).

A. Synthesizing From the Reactive Part of the Output Current

If in the SVD modulation technique, \( \theta_i \) is set to the input voltage phase angle as shown in Fig. 5, the output voltages will also be aligned with the \( d \)-axis of the output synchronous reference frame which is defined by \( \theta_i \), and the generalized modulation technique will be the same as the Alesina and Venturini modulation technique with a more relaxed limitation on \( q_d \) and \( q_q \) [24].

B. Synthesizing From the Active Part of the Output Current

If \( q_q \) is set to zero, as shown in Fig. 6, the output voltage will be aligned with the \( q \)-axis of the output reference frame and the input current will be aligned with the \( d \)-axis of the input reference frame. Therefore, the SVD modulation technique will be the same as the SVM modulation technique [24].

In this case, \( q_d \) controls the voltage gain and \( q_q \) controls the reactive current gain of the matrix converter. Therefore, the input reactive power is limited by the voltage gain and the output reactive power as given by (13)

\[
|Q_i| \leq \frac{1 - G_v}{G_v} |Q_o|
\]

(13)

where \( G_v = V_i/V_o \) is the voltage gain of the matrix converter and \( Q_o \) is the output reactive power.

C. Synthesizing From Both the Active and Reactive Parts of the Output Current

The two previous strategies do not yield the full capability of a matrix converter. To achieve maximum possible input reactive power, both active and reactive parts of the output current can be used to synthesize the input reactive current.

To increase the maximum achievable input reactive current in a matrix converter for a specific output power, its input current...
should be maximized. Since $\mathbf{M}^T$ transforms $I_o$ from the output space onto the input space, to maximize $I_o$, the free parameter $\delta_i$ must be chosen such that $I_o$ is located as close as possible to the direction over which the $\mathbf{M}^T$ gain is maximum, i.e.,

$$\max |I_o| = \max \{ |\mathbf{M}^T I_o| \}$$

subject to:

$$\begin{align*}
V_o &= \mathbf{M}V_i \\
|q_d|, |q_{\delta}| &\leq \sqrt{3} \\
G_{\delta} &< k - q_d + q_{\delta} < 1
\end{align*}$$

(15)

where $k$ is a positive parameter which is used to vary the matrix converter constraint. $k$ can be changed from its minimum possible value (i.e., $k = G_{\delta}$) to its maximum possible value (i.e., $k = 1$) to change the maximum current gain of the matrix converter (i.e., $G_{\text{max}}$) and control its input reactive power.

This optimization problem can be solved with different solvers. However, in this section, a closed form formulation is derived to simplify computations of the control system. It is proved in Appendix A that if $q_d$, $q_{\delta}$, $\delta_i$, and $\delta_o$ are chosen as given in (16), the input current gain of the matrix converter will be equal to its maximum achievable value for a given parameter $k$, voltage gain and output power factor

$$\begin{align*}
q_d &= \min \left\{ k, \frac{\sqrt{3}}{2} \frac{k + \sqrt{4G_{\delta}^2 + k^2 - 4G_{\delta} k \sin \phi_0}}{2} \right\} \\
q_{\delta} &= \text{sign}(\phi_i) \text{sign}(\phi_{\delta}) \min \left\{ k - q_d, \frac{\sqrt{3}}{2}, \frac{q_d G_{\delta} \sin \phi_0}{\sqrt{q_d^2 - G_{\delta}^2 \cos^2 \phi_0}} \right\} \\
\delta_i &= -\text{sign}(\phi_i) \tan^{-1} \left( \frac{\sqrt{q_d^2 - G_{\delta}^2}}{q_d} \right) \\
\delta_o &= \tan^{-1} \left( \frac{q_{\delta}}{q_d} \tan \delta_i \right)
\end{align*}$$

(16)

Figs. 7 and 8 present the maximum current gain and input reactive power in a matrix converter which can be achieved by the three strategies described in this section. As depicted in these figures, the maximum current gain and input reactive power, which can be achieved by the proposed strategy (i.e., strategy 3), are more than that obtained by the other two.

IV. PMS WIND GENERATOR REACTIVE POWER CONTROL

The three methods of controlling the input reactive power of a matrix converter described in the previous section can be used to control the reactive power of a PMS wind generator. A gearless multipole PMS wind generator, which is connected to the output of a matrix converter, is simulated to compare the improvement in the matrix converter input or grid-side reactive power using the proposed strategy. The control block diagram of the system is shown in Fig. 9, and its parameters are listed in Table I. The simulations are performed using PSCAD/EMTDC software.

To control the generator torque and speed, generator quantities are transferred onto the synchronous reference frame such that the rotor flux is aligned with the $d$–axis of the $dq0$ reference frame. Therefore, $I_{qs}$ will become proportional to the generator torque, and $I_{qd}$ can be varied to control the generator output reactive power. Usually, $I_{qd}$ is set to zero to minimize the generator current and losses. However, in this section, the effect of $I_{qd}$ on the input reactive power is also studied, and a new control structure is proposed which can control the generator reactive power to improve the reactive power capability of the system [27].

A. Fixed $I_{qd}$

If $I_{qd}$ is set to zero, the generator output current and losses will be minimized. However, since the reactance of a syn-

Fig. 10. Phasor diagram of PMSG for different values of $I_{gd}$. (a) PMSG equivalent circuit. (b) $I_{gs} = 0$. (c) $I_{gd} > 0$.

Although the maximum achievable grid-side reactive power is improved by the proposed strategy, at low wind speed conditions, the system reactive power capability will be decreased severely which may decrease the system voltage quality and stability. Since, in the proposed strategy, the grid-side reactive current is made from both active and reactive parts of the generator-side current, control of the generator-side reactive power
Fig. 12. Grid-side maximum achievable reactive power for different values of $I_{gd}$.

Fig. 13. Proposed control structure which uses $I_{gd}$ and matrix converter synchronously to control the grid-side reactive power.

will be effective in increasing the grid-side reactive power at all wind speed conditions.

As shown in Fig. 10(c), an increase of $I_{gd}$ from zero will increase the generator current and decrease its terminal voltage while its effect on the output active power can be neglected. On the other hand, as depicted in Fig. 7(c), decreasing the matrix converter voltage gain will increase the maximum current gain. Therefore, increasing $I_{gd}$ will increase the grid-side reactive power and improve the system reactive power capability. Fig. 12 shows the maximum achievable grid-side reactive power if $I_{gd}$ is set to a value different from its maximum-allowable value. It can be seen from this figure that if the generator free reactive power capacity is used, a nearly uniform maximum grid-side reactive power can be achieved at all wind speeds.

Since increasing $I_{gd}$ will increase the generator losses, a new control structure is also proposed in Fig. 13 which controls $I_{gd}$ if and only if the maximum grid-side reactive power, which can be achieved for $I_{gd} = 0$, is not sufficient. The proposed structure consists of two reactive gain and reactive current control loops which are controlled by a single reactive power controller. The reactive gain loop controls the matrix converter current gain or $\phi_1$ by changing the absolute value of parameter $k$ defined in (16). The sign of $k$ defines the sign of $\phi_1$ or the sign of the grid-side reactive power. When parameter $k$ is lower than its maximum value (i.e., $k = 1$), the reactive current loop, which controls $I_{gd, \text{ref}}$, is open by the dead zone element, and the reactive gain loop controls the matrix converter current gain. When $k$ reaches its maximum value, the reactive gain loop will be opened due to the saturation of the matrix converter current gain, and the reactive current loop will be controlled by the same controller.

The proposed structure defines $I_{gd, \text{ref}}$ in Fig. 9, and $G_s$ define the desired matrix converter output voltage required to control the generator. This required voltage is generated by the generator current controllers in Fig. 9.

Figs. 14 and 15 depict the simulation results for the proposed control structure for two different generator speeds. The controller used in these simulations for the grid-side reactive power control is a simple adaptive controller (SAC) which is presented in Appendix B. It can be seen from these figures that the controller increases $I_{gd}$ to track the desired grid-side reactive power, if the maximum achievable grid-side reactive power for $I_{gd} = 0$ is not sufficient. An increase in $I_{gd}$ will decrease the generator terminal voltage and increase the generator losses.

V. CONCLUSION

In this paper, a new control strategy is proposed to increase the maximum achievable grid-side reactive power of a matrix converter-fed PMS wind generator. Different methods for controlling a matrix converter input reactive power are investigated.
It is shown that in some modulation methods, the grid-side reactive current is made from the reactive part of the generator-side current. In other modulation techniques, the grid-side reactive current is made from the active part of the generator-side current. In the proposed method, which is based on a generalized SVD modulation method, the grid-side reactive current is made from both active and reactive parts of the generator-side current.

In existing strategies, a decrease in the generator speed and output active and reactive power, will decrease the grid-side reactive power capability. A new control structure is proposed which uses the free capacity of the generator reactive power to increase the maximum achievable grid-side reactive power. Simulation results for a case study show an increase in the grid-side reactive power at all wind speeds if the proposed method is employed.

**APPENDIX A**

**MAXIMUM INPUT CURRENT GAIN**

The input current gain of a matrix converter for a specific output voltage and current will be maximum if the input power factor is minimum or \(\tan \phi_i\) is maximum. For this purpose, the following results can be deduced from Fig. 3:

\[
G_i^2 = \frac{V_{oq}^2}{V_{id}^2} = \frac{V_{oq}^2 + V_{od}^2}{V_{id}^2} = \frac{q_d^2 \cos^2 \delta_i + q_q^2 \sin^2 \delta_i}{q_d^2} \\
\Rightarrow \tan \delta_i = \pm \sqrt{\frac{q_q^2 - G_i^2}{G_i^2 - q_d^2}} \tag{17}
\]

\[
\tan \delta_o = \frac{V_{oq} V_{id}}{V_{od} V_{id}} = \frac{q_q V_{id}}{q_d V_{id}} \tag{18}
\]

\[
\tan (\phi_i + \delta_o) = \frac{I_{id}}{I_{iq}} = \frac{q_d I_{id}}{q_q I_{iq}} = \frac{q_d}{q_q} \tan (\phi_i + \delta_o) \tag{19}
\]

\(\tan \phi_i\) can be obtained as (20) by substituting (17) and (18) into (19):

\[
\tan \phi_i = \frac{1}{G_i} \left[ + \sqrt{(q_q^2 - G_i^2)(G_i^2 - q_d^2)} + q_d q_q \tan \phi_i \right]. \tag{20}
\]

When the SVD modulation does not reach its constraints (i.e., \(q_d \leq \{k, \sqrt{3}/2\}\) and \(q_q \leq \{k - q_d, \sqrt{3}/2\}\), the maximum input current and maximum of \(\tan \phi_i\) will be achieved if the output current is directed on the direction over which the \(M^t\) gain is maximum, that is, \(\delta_o = -\phi_i\) and \(\delta_i = -\phi_i\). Therefore, from (17), \(q_d\) and \(q_q\) are calculated as follows:

\[
q_d = \pm \frac{q_d G_i \sin \phi_i}{\sqrt{q_d^2 - G_i^2 \cos^2 \phi_i}}. \tag{21}
\]

However, if the SVD modulation reaches its constraints, \(q_q\) can be replaced by \(+ (k - q_d)\) in (20):

\[
\tan \phi_i = \frac{1}{G_i} \left[ + \sqrt{(q_q^2 - G_i^2)(G_i^2 - (k - q_d)^2)} + q_d (k - q_d) \tan \phi_i \right]. \tag{22}
\]

Equation (22) concludes that to obtain maximum input current gain, \(\delta_i\) and \(q_q\) must be selected as

\[
\begin{align*}
\tan \phi_o > 0, \tan \phi_i > 0 &\Rightarrow \delta_i < 0, q_q > 0 \\
\tan \phi_o > 0, \tan \phi_i < 0 &\Rightarrow \delta_i < 0, q_q < 0 \\
\tan \phi_o < 0, \tan \phi_i > 0 &\Rightarrow \delta_i < 0, q_q < 0 \\
\tan \phi_o < 0, \tan \phi_i < 0 &\Rightarrow \delta_i > 0, q_q > 0
\end{align*} \tag{23}
\]

and \(q_d\) be a positive number as

\[
\frac{\partial \tan \phi_i}{\partial q_d} = 0 \Rightarrow q_d = \frac{k + \sqrt{k^2 + 4G_i^2 - 4kG_i \sin |\phi_i|}}{2}. \tag{24}
\]
Once $q_d$ is obtained from (24), $q_q$ and $\delta_i$ can be found from (17), (18), (21), and (23) as follows:

\[
q_d = \min \left\{ \sqrt{\frac{k}{2}} \sqrt{k^2 + 4G_2^2 + 4G_2k\sin \phi_e} \right\}
\]

\[
q_q = \text{sign}(\phi_1) \text{sign}(\phi_e) \min \left\{ k - q_d, \sqrt{\frac{k_2}{2}} \sqrt{G_2^2 - G_2^2 \cos^2 \phi_e} \right\}
\]

\[
\delta_i = -\text{sign}(\phi_1) \tan^{-1} \left( \frac{\sqrt{G_2^2 - G_1^2}}{G_2 - G_1} \right)
\]

\[
\delta_\nu = \tan^{-1} \left( \frac{2\delta_e}{q_d \tan \phi_e} \right).
\]

(25)

Changing $k$ results in a variable $\tan \phi_e$ and variable maximum gain. Equation (25), along with (9), define all required parameters for the SVD modulation to achieve maximum reactive current at the grid side.

**APPENDIX B**

**SIMPLE ADAPTIVE CONTROLLER (SAC)**

Most of real plants can be controlled with a simple low-order linear controller. A SAC is somehow a combination of a linear and an adaptive controller which simply guarantees the stability of the system with no difficult constraints [28].

If the state space of an Almost Strictly Positive Real (APSR) plant is as follows:

\[
\begin{align*}
\dot{X}_p &= A_p X_p + B_p u_p \\
y_p &= C_p X_p
\end{align*}
\]

Then, the plant can follow the output of any SISO stable reference model of (27) with the input control law of (28) and the adaptive law of (29).

\[
\begin{align*}
X_m &= A_m X_m + B_m u_m \\
y_m &= C_m X_m
\end{align*}
\]

\[
u_p = k_e (y_m - y_p) + k_x X_m + k_u u_m
\]

\[
\begin{align*}
k_e &= -\gamma_1 e^2 \\
k_x &= -\Gamma_2 X_m e \\
k_u &= -\gamma_3 u_m e
\end{align*}
\]

(27) (28) (29)

where $\gamma_1$, $\Gamma_2$, and $\gamma_3$ are the adaptation gains.

The following lemma is useful to obtain an ASPR plant.

**Lemma:** If $G_p$ is any nonlinear system, and $H_c$ is any stabilizing controller in the form of Fig. 16(a), then the augmented plant of Fig. 16(b) is almost strictly positive real [28].

In this paper, the stabilizing linear controller, reference model, control and adaptive laws are selected as follows:

\[
H_c = 0.2 \left( \frac{0.01s + 1}{s} \right)
\]

\[
H_c^{-1} = \frac{5s}{0.01s + 1}
\]

\[
G_m = \frac{y_m}{u_m} - \frac{1}{0.01s + 1}
\]

\[
\begin{align*}
\gamma_1 &= 10^3 \\
\Gamma_2 &= 10^3.
\end{align*}
\]

(30)

The reference model is selected a simple time constant of 0.01, which is larger than the reactive gain and reactive current loops time constants in Fig. 13, and does not pass the second harmonic of the grid-side reactive power. The adaptive gains are chosen by trial and error using simulations in order to achieve a good rate of convergence.

**REFERENCES**

Hossein Hojabri was born in Kerman, Iran, in 1982. He received the B.Sc. degree in electrical engineering from Isfahan University of Technology, Isfahan, Iran, in 2004 and the M.Sc. degree in electrical engineering from Sharif University of Technology, Tehran, Iran, in 2006, where he is currently pursuing the Ph.D. degree in electrical engineering.

His research interests include the application of power electronics in power systems, power quality, and renewable energy systems.

Hossein Mohktari (M’03) was born in Tehran, Iran, on August 19, 1966. He received the B.Sc. degree in electrical engineering from Tehran University, Tehran, Iran, in 1989, the M.Sc. degree in power electronics from the University of New Brunswick, Fredericton, NB, Canada, in 1994, and the Ph.D. degree in power electronics/power quality from the University of Toronto, Toronto, ON, Canada, in 1999.

From 1989 to 1992, he was with the Consulting Division of Power Systems Dispatching Projects, Electric Power Research Center Institute. Since 2000, he has been with the Department of Electrical Engineering, Sharif University of Technology, Tehran, Iran, where he is currently a Professor. He is also a Senior Consultant to several utilities and industries. His research interests include power quality, power electronics, and its application in power distribution systems, microgrids, wide-area measurements, and smart grids.

Liuchen Chang (S’87–M’92–SM’99) received the B.S. degree in electrical engineering from Northern Jiaotong University, Beijing, China, in 1982, the M.Sc. degree in electrical engineering from the China Academy of Railway Sciences, Beijing, in 1984, and the Ph.D. degree in electrical engineering from Queen’s University, Kingston, ON, Canada, in 1991.

Currently, he is a Professor in the Department of Electrical and Computer Engineering, University of New Brunswick, Fredericton, NB, Canada, where he has been since 1992. He has published more than 200 papers in technical journals and conference proceedings and two books. His principal research interests and experience include distributed generation, renewable energy conversion, power-electronic converters, along with the analysis and design of electrical machines.

Prof. Chang is a recipient of the CanWEA R. J. Templin Award for his research achievements in wind energy technologies. He is a Registered Professional Engineer of APEGNB and a Fellow of the Canadian Academy of Engineering.
